

I²S bus specification

1.0 INTRODUCTION

Many digital audio systems are being introduced into the consumer audio market, including compact disc, digital audio tape, digital sound processors, and digital TV-sound. The digital audio signals in these systems are being processed by a number of (V)LSI ICs, such as:

- A/D and D/A converters;
- digital signal processors;
- error correction for compact disc and digital recording;
- digital filters;
- digital input/output interfaces.

Standardized communication structures are vital for both the equipment and the IC manufacturer, because they increase system flexibility. To this end, we have developed the inter-IC sound (I²S) bus – a serial link especially for digital audio.

2.0 BASIC SERIAL BUS REQUIREMENTS

The bus has only to handle audio data, while the other signals, such as sub-coding and control, are transferred separately. To minimize the number of pins required and to keep wiring simple, a 3-line serial bus is used consisting of a line for two time-multiplexed data channels, a word select line and a clock line.

Since the transmitter and receiver have the same clock signal for data transmission, the transmitter as the master, has to generate the bit clock, word-select signal and data. In complex systems however, there may be several transmitters and receivers, which makes it difficult to define the master. In such systems, there is usually a system master controlling digital audio data-flow between the various ICs. Transmitters then, have to generate data under the control of an external clock, and so act as a slave. Figure 1 illustrates some simple system configurations and the basic interface timing. Note that the system master can be combined with a transmitter or receiver, and it may be enabled or disabled under software control or by pin programming.

3.0 THE I²S BUS

As shown in Figure 1, the bus has three lines:

- continuous serial clock (SCK);
- word select (WS);
- serial data (SD);

and the device generating SCK and WS is the master.

3.1 Serial Data

Serial data is transmitted in two's complement with the MSB first. The MSB is transmitted first because the transmitter and receiver may have different word lengths. It isn't necessary for the transmitter to know how many bits the receiver can handle, nor does the receiver need to know how many bits are being transmitted.

When the system word length is greater than the transmitter word length, the word is truncated (least significant data bits are set to '0') for data transmission. If the receiver is sent more bits than its word length, the bits after the LSB are ignored. On the other hand, if the receiver is sent fewer bits than its word length, the missing bits are set to zero internally. And so, the MSB has a fixed position, whereas the position of the LSB depends on the word length. The transmitter always sends the MSB of the next word one clock period after the WS changes.

Serial data sent by the transmitter may be synchronized with either the trailing (HIGH-to-LOW) or the leading (LOW-to-HIGH) edge of the clock signal. However, the serial data must be latched into the receiver on the leading edge of the serial clock signal, and so there are some restrictions when transmitting data that is synchronized with the leading edge (see Figure 2 and Table 1).

3.2 Word Select

The word select line indicates the channel being transmitted:

- WS = 0; channel 1 (left);
- WS = 1; channel 2 (right).

WS may change either on a trailing or leading edge of the serial clock, but it doesn't need to be symmetrical. In the slave, this signal

is latched on the leading edge of the clock signal. The WS line changes one clock period before the MSB is transmitted. This allows the slave transmitter to derive synchronous timing of the serial data that will be set up for transmission. Furthermore, it enables the receiver to store the previous word and clear the input for the next word (see Figure 1).

4.0 TIMING

In the I²S format, any device can act as the system master by providing the necessary clock signals. A slave will usually derive its internal clock signal from an external clock input. This means, taking into account the propagation delays between master clock and the data and/or word-select signals, that the total delay is simply the sum of:

- the delay between the external (master) clock and the slave's internal clock; and
- the delay between the internal clock and the data and/or word-select signals.

For data and word-select inputs, the external to internal clock delay is of no consequence because it only lengthens the effective set-up time (see Figure 2). The major part of the time margin is to accommodate the difference between the propagation delay of the transmitter, and the time required to set up the receiver.

All timing requirements are specified relative to the clock period or to the minimum allowed clock period of a device. This means that higher data rates can be used in the future.

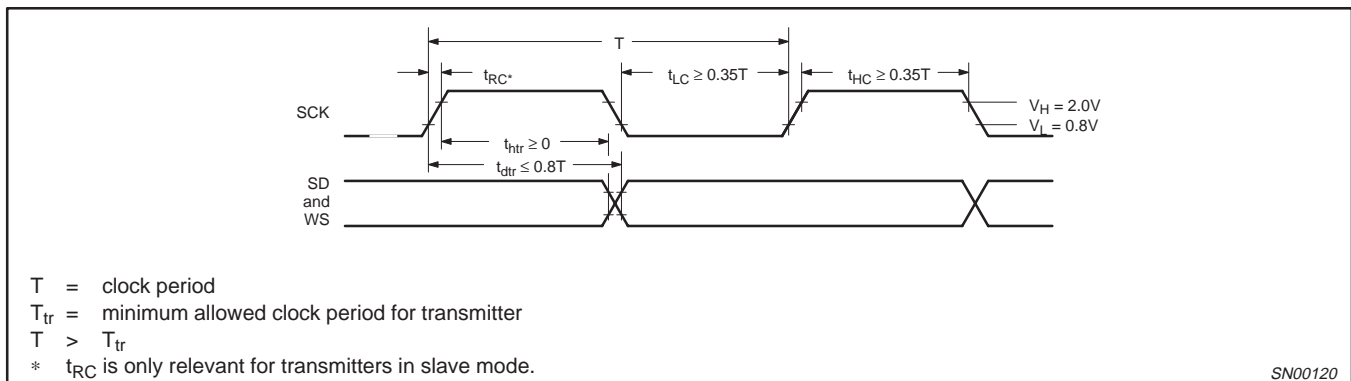

Figure 2. Timing for I²S Transmitter

I²S bus specification

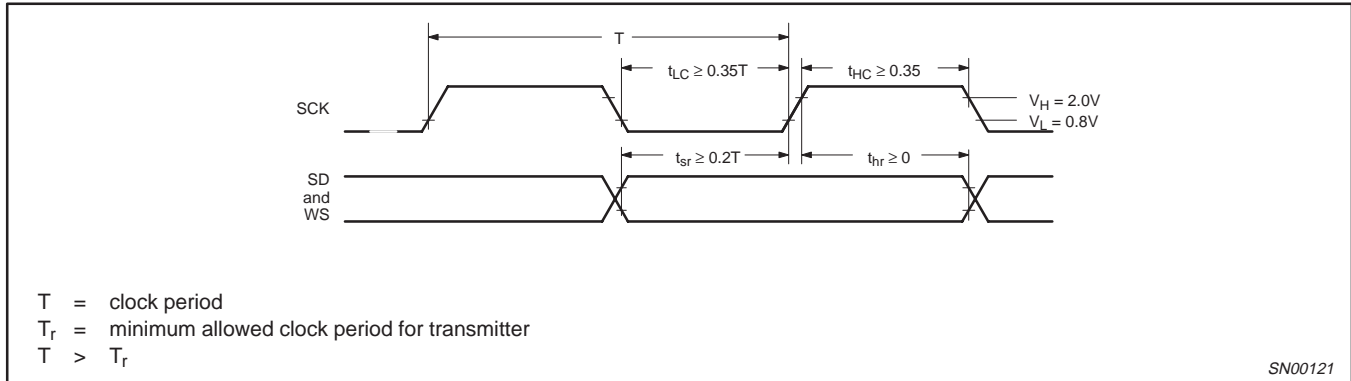

Figure 3. Timing for I²S Receiver

Note that the times given in both Figures 2 and 3 are defined by the transmitter speed. The specification of the receiver has to be able to match the performance of the transmitter

Example: Master transmitter with data rate of 2.5MHz (±10%) (all values in ns)

	MIN	TYP	MAX	CONDITION
clock period T	360	400	440	$T_{tr} = 360$
clock HIGH t_{HC}	160			min $> 0.35T = 140$ (at typical data rate)
clock LOW t_{LC}	160			min $> 0.35T = 140$ (at typical data rate)
delay t_{dtr}			300	max $< 0.80T = 320$ (at typical data rate)
hold time t_{hr}	100			min > 0
clock rise-time t_{RC}			60	max $> 0.15T_{tr} = 54$ (only relevant in slave mode)

Example: Slave receiver with data rate of 2.5MHz (±10%) (all values in ns)

	MIN	TYP	MAX	CONDITION
clock period T	360	400	440	$T_{tr} = 360$
clock HIGH t_{HC}	110			min $< 0.35T = 126$
clock LOW t_{LC}	110			min $< 0.35T = 126$
set-up time t_{sr}	60			min $< 0.20T = 72$
hold time t_{hr}	0			min < 0

I²S bus specification

Table 1. Timing for I²S transmitters and receivers

	TRANSMITTER				RECEIVER				NOTES
	LOWER LIMIT		UPPER LIMIT		LOWER LIMIT		UPPER LIMIT		
	MIN	MAX	MIN	MAX	MIN	MAX	MIN	MAX	
Clock period T	T_{tr}				T_r				1
MASTER MODE: clock generated by transmitter or receiver: HIGH t_{HC} LOW t_{LC}	$0.35T_{tr}$ $0.35T_{tr}$				$0.35T_{tr}$ $0.35T_{tr}$				2a 2a
SLAVE MODE: clock accepted by transmitter or receiver: HIGH t_{HC} LOW t_{LC} rise-time t_{RC}		$0.35T_{tr}$ $0.35T_{tr}$		$0.15T_{tr}$		$0.35T_r$ $0.35T_r$			2b 2b 3
TRANSMITTER: delay t_{dtr} hold time t_{htr}	0			$0.8T$					4 3
RECEIVER: set-up time t_{sr} hold time t_{hr}						$0.2T_r$ 0			5 5

All timing values are specified with respect to high and low threshold levels.

NOTES:

1. The system clock period T must be greater than T_{tr} and T_r because both the transmitter and receiver have to be able to handle the data transfer rate.
- 2a. At all data rates in the master mode, the transmitter or receiver generates a clock signal with a fixed mark/space ratio. For this reason t_{HC} and t_{LC} are specified with respect to T.
- 2b. In the slave mode, the transmitter and receiver need a clock signal with minimum HIGH and LOW periods so that they can detect the signal. So long as the minimum periods are greater than $0.35T_r$, any clock that meets the requirements can be used (see Figure 3).
3. Because the delay (t_{dtr}) and the maximum transmitter speed (defined by T_{tr}) are related, a fast transmitter driven by a slow clock edge can result in t_{dtr} not exceeding t_{RC} which means t_{htr} becomes zero or negative. Therefore, the transmitter has to guarantee that t_{htr} is greater than or equal to zero, so long as the clock rise-time t_{RC} is not more than t_{RCmax} , where t_{RCmax} is not less than $0.15T_{tr}$.
4. To allow data to be clocked out on a falling edge, the delay is specified with respect to the rising edge of the clock signal and T, always giving the receiver sufficient set-up time.
5. The data set-up and hold time must not be less than the specified receiver set-up and hold time.
